

# TIFOSI: A Quantum Scattering Simulation

Jan Harms

INFN, Sezione di Firenze

# Why TIFOSI?

1. We should be able to model realistic OPAs. Down-conversion is not yet described in LG/HG bases.
2. We want to understand what happens to quantum fields when they interact with cavities subject to scattering and clipping.
3. One day we want to do really good with squeezing and QND (and therefore care about details).
4. You want an alternative approach to compare with LG/HG quantum simulations (Finesse, MIST).

# TIFOSI Building Blocks

Phase matching

Down-conversion

Pump mode

Squeezing  
crystal

Clipping loss

Mirror aberration

Eigenmodes

Cavity

Cavity lock

Mode matching

OPA

Homodyne  
detector

Local oscillator

# Classical Versus Quantum FFT

Oscar, SIS, Fog

Fields =  
N-dim vectors

Calculate  
propagated  
fields

Calculate fields  
interacting with cavities  
as stationary solution

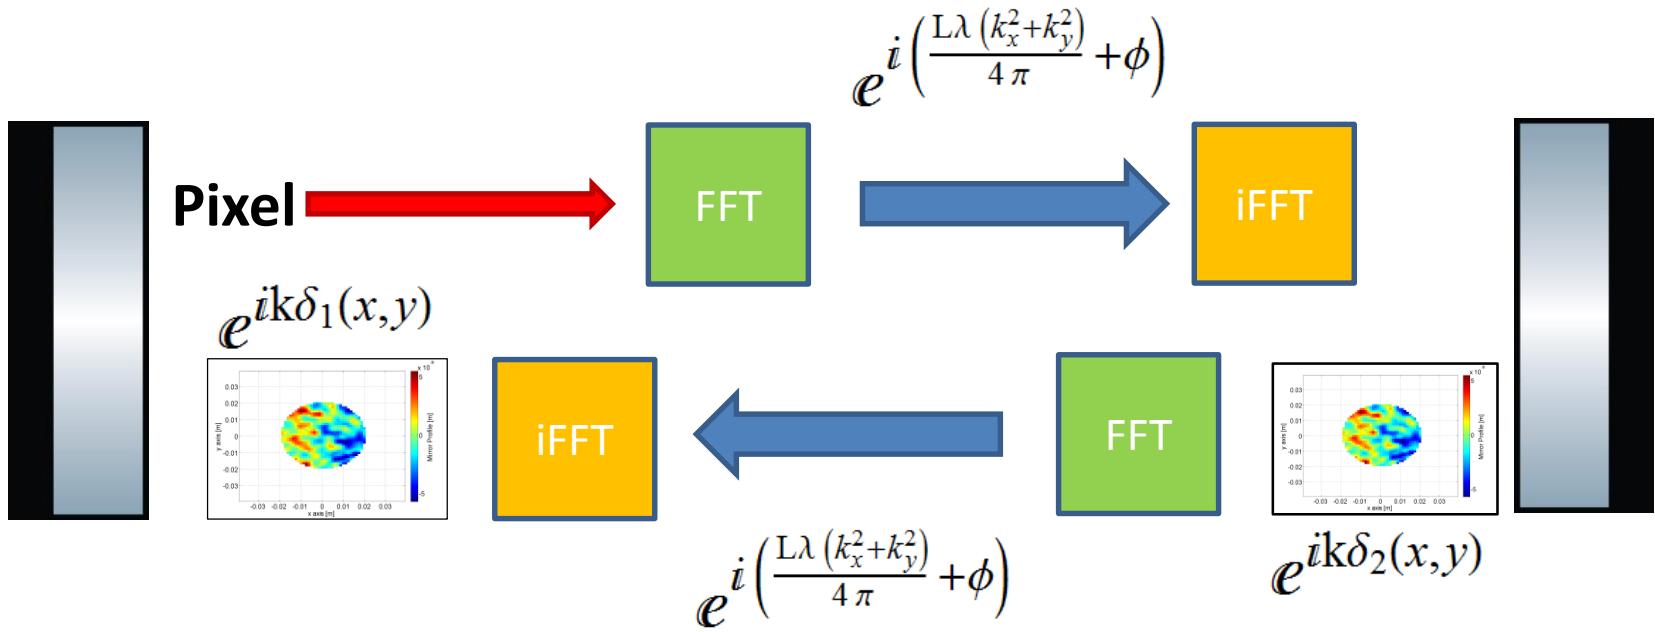

TIFOSI

Fields =  
NxN-dim matrices

Calculate propagated  
fields starting with  
vacuum field

Directly calculate cavity  
resonance  
 $1/(1-\text{Roundtrip})$

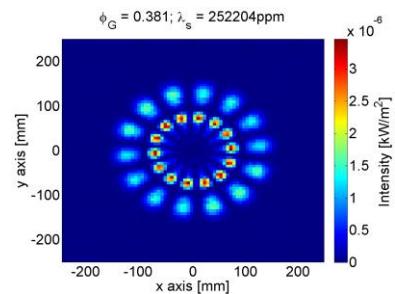

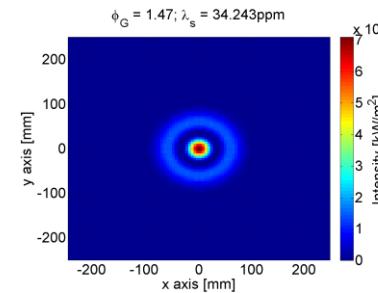

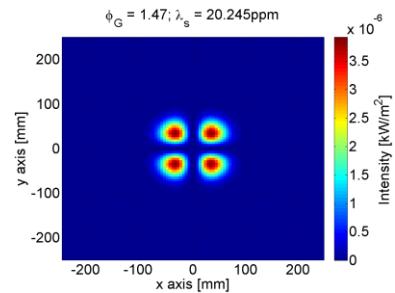

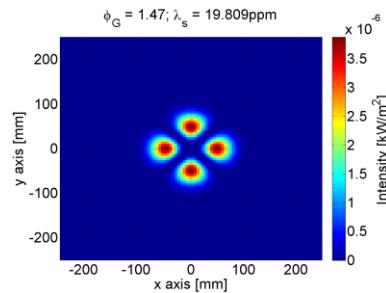

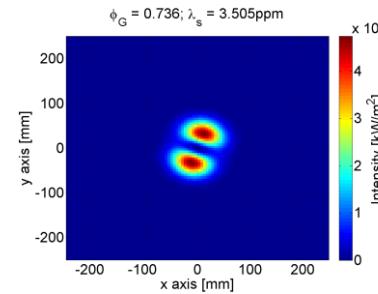

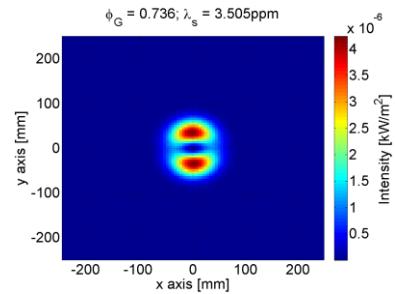

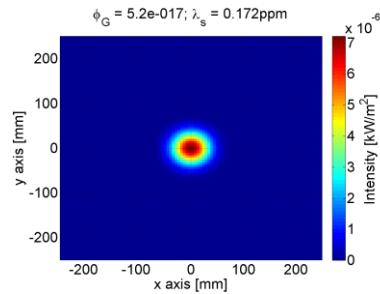

# Building a Round-Trip Matrix

Jerome Degallaix said:  
Repeat this procedure  
for entire pixel basis.

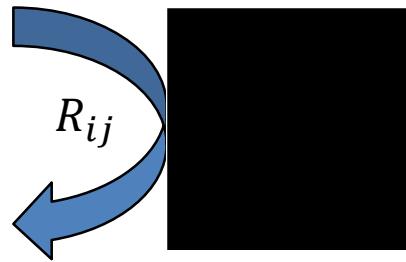

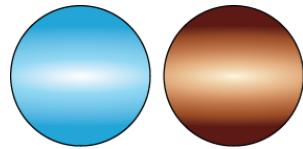

This is the fastest and (therefore)  
numerically most accurate procedure.

# Cavity Eigenmodes

# Quantum Noise and Cavities

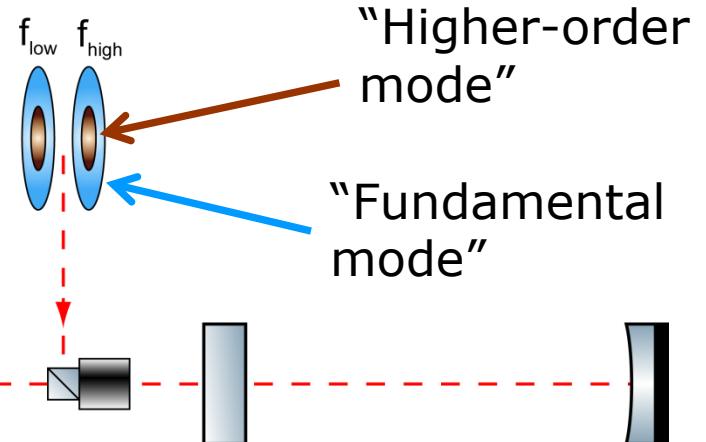

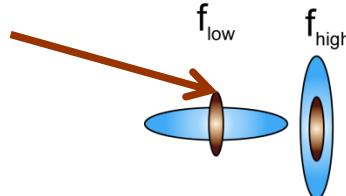

$R_{ij}$  eigenvectors:

Cavity couples spatial modes since its eigenmodes are different from “external” basis.

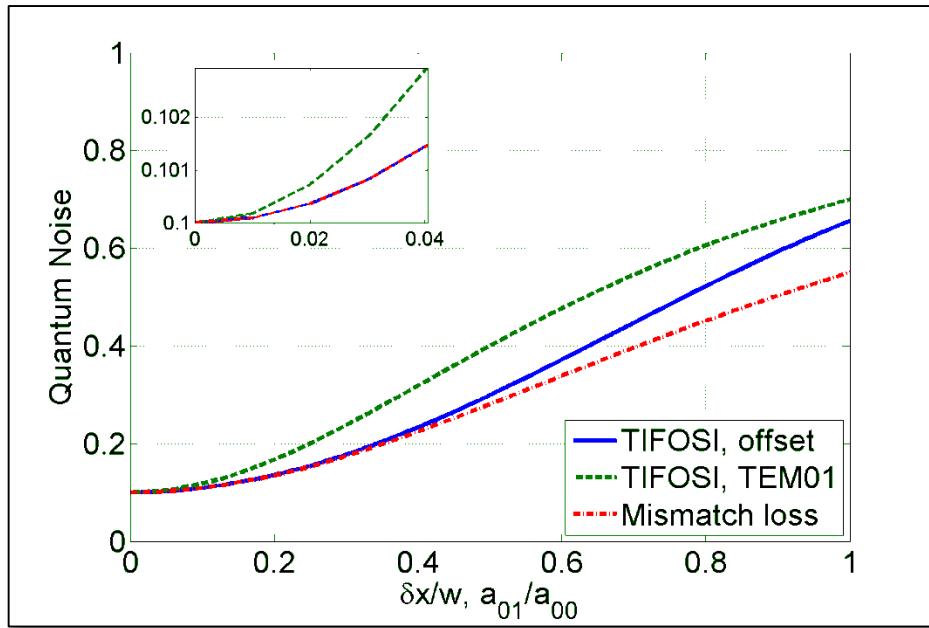

Not all squeezing ellipses will be rotated in the same way.

Excess noise

# The Ideal OPA

Variations of local oscillator

Ideal means:

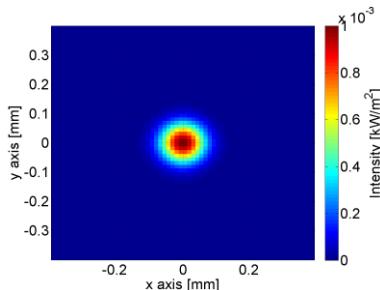

- (1)The OPA has no clipping or absorption loss.
- (2)The eigenmodes are LG/HG, or as close to this as possible (LG/HG cannot be represented by Fourier simulations)
- (3)Pump is a plane wave.

**RED:** QN according to mode-mismatch loss produced by TEM01 content  
**GREEN:** QN according to TIFOSI produced by TEM01 content  
**BLUE:** QN according to TIFOSI produced by LO offset

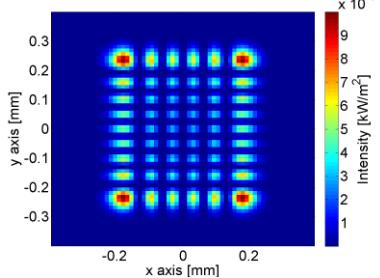

# LG/HG to DFT

If you have the guts to guess  
OPA eigenmodes: HG

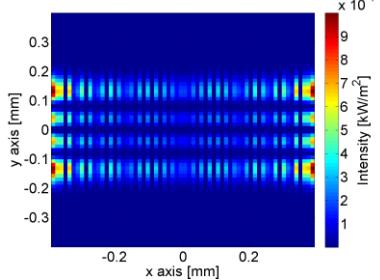

TEM 0 0

TEM 8 5

TEM 3 28

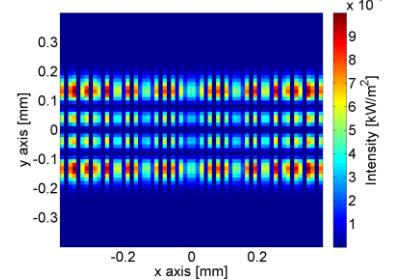

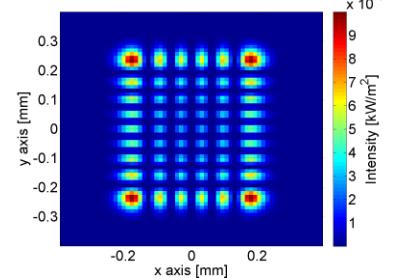

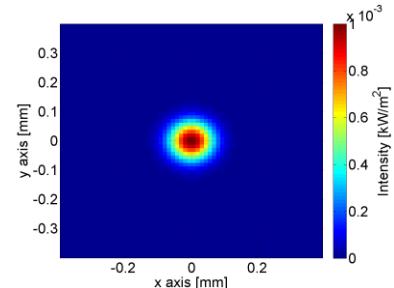

**Gram-Schmidt orthogonalization  
(QR decomposition)**

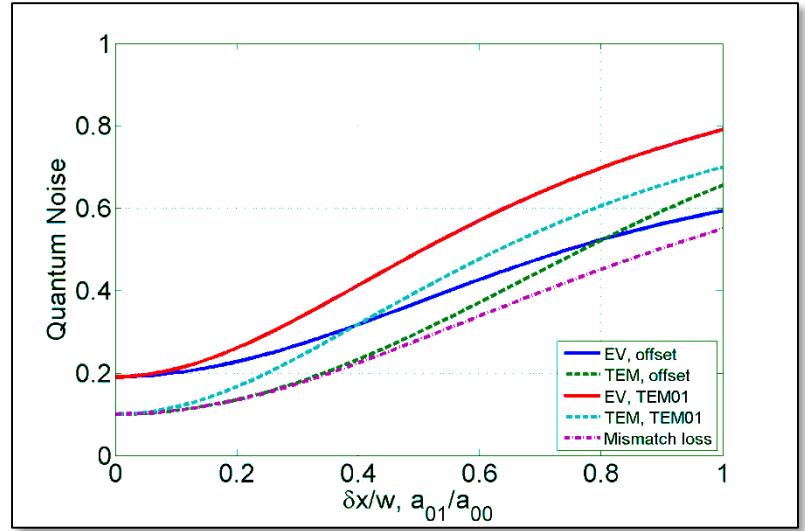

This transform must be unitary,  
otherwise you have artificial  
loss.

DFT

# A Realistic OPA

- (1) Calculate OPA eigenmodes.
- (2) Expand pump beam into plane waves.
- (3) Calculate OPA output for each plane wave of the pump for each eigenmode.
- (4) Sum contributions from all plane waves of the pump.

Items (1) and (3)  
implemented,  
assuming plane-wave  
pump (EV curves)

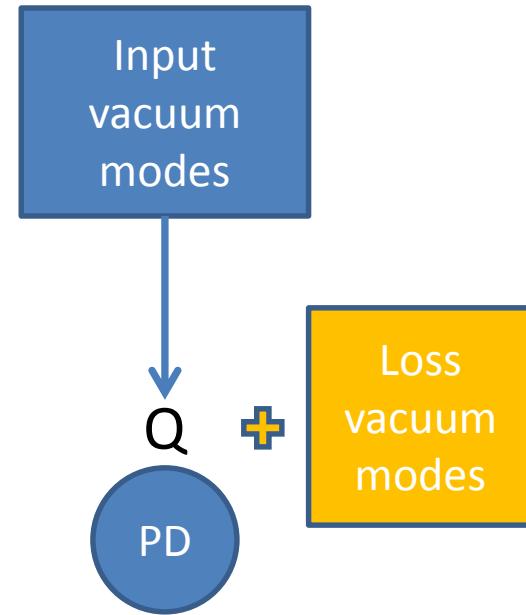

# Optical Loss

**Current implementation in TIFOSI:**

Vector (1-Loss) = diagonal of  $(Q Q^*)$ , where  $Q$  is the quantum field at the photodiode.

**The problem is that this loss vector does not tell you anything about the nature of the injected loss field (whether it is squeezed or not).**

Therefore, what about loss that occurs inside an OPA?

# Aliasing Problem in FFT Codes

**Simple understanding of aliasing based on rays:**

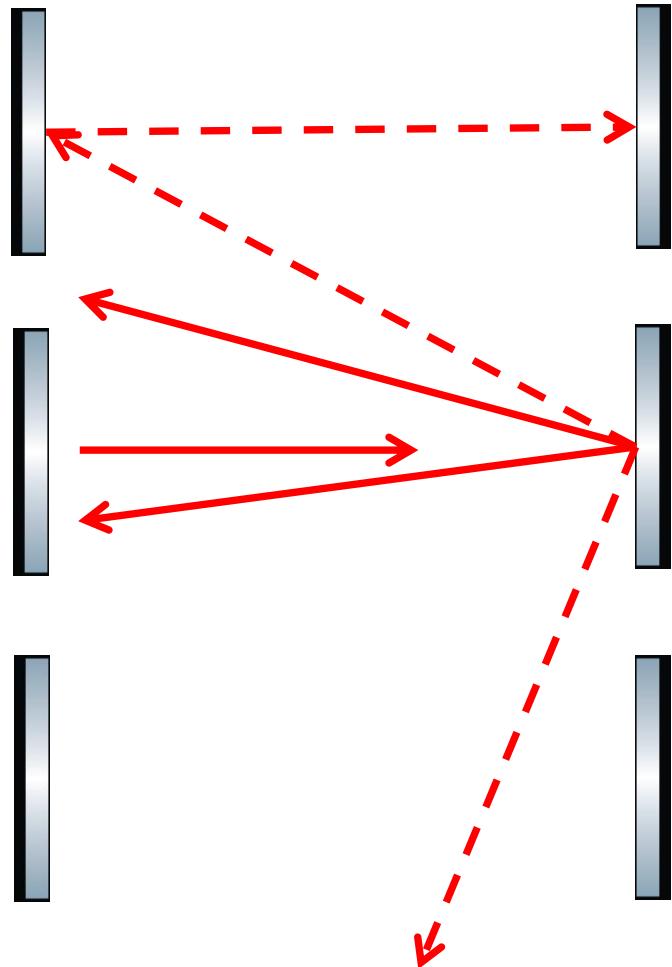

- (1) DFT can only simulate cyclic systems.
- (2) Rays can hit a copy of a mirror next door, which is indistinguishable from the “real” mirror.

**Anti-aliasing methods used:**

- (1) Set “rays” to zero that propagate at too large angle: JOSA A 31, 652 (2014)
- (2) Use FFT-DI (direct integration) propagation of fields: Applied Optics 45, 1102 (2006).

**Limitations:**

- (1) Setting ray (i.e. plane-wave) amplitudes to zero can lead to systematic errors.
- (2) FFT-DI does not seem to work for short cavities.

# Future Work

- (1) Study alternative anti-aliasing methods (has been done by other people to some extent, but not very carefully).
- (2) Ask experimentalists what I can do for them.
- (3) Suggest to experimentalists what would be nice to measure (e.g. dedicated study of mode mismatch including beam jitter to quantum noise,).
