

Astrophysical signals and noise in pulsar timing array observations

Ryan M. Shannon

Astronomy and Space Science www.csiro.au

Outline

- Noise in pulsar timing measurements
- Interpreting the Parkes Pulsar timing array limit on the GWB in the context of SMBH/Galaxy evolution models (Shannon et al. 2013, Science)
 - Bottom line: We are now using GWs to study supermassive black holes!
- Searches for continuous waves in PTA data
- Advancing the PTA detector
 - More pulsars, more collecting area, judicious observing strategy

Contributions to Pulsar Arrival Times

- Pulsar spindown
- Intrinsic variation in shape and/or phase of emitted pulses (jitter)
- Reflex motion from companions.
- Pulsar position, proper motion, distance
- Gravitational Waves
- Warm electrons in the ISM
- Solar system ephemeris
- Errors in time standards

Pulsar

TIME

ntensity

O. Löhmer et al .: Frequency evoluti

The PPTA Project

Parkes (Australia) 64 metre telescope

- ~ 20 pulsars south of declination +24 degrees (10 year datasets+ archival data on some pulsars)
- First data release published in 2013 raw data and (processed) TOAs can be found at data.csiro.au
- Most pulsars show evidence red-noise process and many show excess white noise

Year

Pulse-shape variations

- Expect white noise based on finite SNR of observations (radiometer noise)
- Individual pulses look different from one another but converge to stable shape
- These variations bias estimates of TOA uncertainties
- Shape variations correlate over wide bandwidths
- Jitter noise

Accounting for pulse-shape variations in timing models

- In general jitter noise level scales proportion to N_p^{-1/2}. Common between different telescopes/instruments.
- Including physically derived errors produces Gaussian datasets with lower white noise levels.
- Introduces 10-200 ns of additional rms error per hr^{-1/2} of observation.

CSIRC

Red noise

- Most young pulsars show red spin noise
 - Rotation instabilities?
 - Magnetospheric torque changes?
 - Open question: is this a generic property of MSPs too?
 - Can have similar spectral properties to GWB
- Solution: need to (at least) model the presence of red noise in datasets
- Triage bad pulsars

The interstellar medium

Largest red signal in data set: Variations in dispersion measure (DM). Proportional to λ^2 .

Need to remove **red signal** associated with DM variations without removing red signal associated with GWB

Include model of λ independent in DM correction algorithm (Shannon 2011, Keith et al. 2013, Lee et al. 2014, Lentati et al. 2014)

Multi-path propagation

- Multi-path propagation causes broadening of pulse signal.
 - Proportional to λ^2 to $\lambda^{6.4}$
- Broadening is variable with time
- Strongest for distant pulsars observed at low frequencies
- Solution:
 - Observe at higher radio frequency
 - Explore mitigation methods (Demorest 2012)

Sources of GWs in Pulsar Band

•Sensitive to GWs with frequencies between 3 and 300 nHz (get TOAs every week for 10 years)

•Massive Black Hole Binaries (Jaffe & Backer 2003, Sesana et al. 2008, Ravi et al. 2012)

•Cosmic Strings and Super Strings (Damour & Vilenkin 2005, Sandias et al. 2012)

•Cosmological QCD Phase Transition (Witten 2007, Caprini et al. 2010).

A Recipe for producing a GWB from SMBH

- Black holes formed early in the universe at the centres of the first galaxies
- After galaxies merge, black holes dynamically dragged to centre
- When MBHs get close, they become prodigious emitters of GWs
- After merger, resultant GH gains mass through accretion (Quasar phase)
- Process repeats many times for each current galaxy (10?).

M. Volonteri

Why do we care about supermassive black holes?

- How do galaxies form? Why do today's galaxies look the way they do? What did the first galaxies look like?
- Supermassive black holes play a crucial role in governing the formation of galaxies through the process of feedback.
- There is a strong correlation between SMBH properties and the properties of their host Galaxies.
- It is difficult to observe merging binary supermassive black holes in any other way.
 - Too close together to resolve using optical telescopes.
 - Reside in dense environments.

The Stochastic Background

The stochastic background is the superposition of GWs from many sources

Background induces **red power spectrum** in residuals (more power at lowest frequency of GWs).

The background is characterized by a strain amplitude spectrum.

For MBH binary the spectrum is expected to be:

$$h_c(f) = 10^{-15} \left(\frac{f}{1 \text{ yr}^{-1}} \right)^{-2/3}$$

RMS contributions to residuals ~**20 ns** over 5 years: need to combine signal from a group of pulsars (pulsar timing array, PTA).

Relative Angle

Time (arb)

Constraining the GWB

Developed a **detection statistic** (DS) based on power spectra of residual time series

- Easier to deal with power spectra
- Account for spectral leakage
- DS is estimator of strength of GWB
 - Non-negatively biased (does not underestimate strength of the GWB strength)
- Combine pulsars: weighted sum of each spectral bin in the PTA.
- Model: accounts for all plausible signals
 - Common GW signal
 - White noise (radiometer + pulse shape variations + scintillation)
 - Red noise (Spin noise ++)

- A_b: detection statistic
- P_i: measured power spectra
- W_i : white noise
- g_i: shape of GWB
- M_i: model of red noise

$$\hat{A}_b^2 = \frac{\sum_{ij} (P_j(f_i) - W_j) g_j(f_i) / M_j^2(f_i)}{\sum_{ij} [g_j(f_i) / M_j(f_i)]^2}$$

An Algorithm for Constraining the GWB

- Calculate test statistic DS for real data (*observed DS*)
- Simulations
 - Form ideal site TOAs
 - Add white noise consistent with observations
 - Add GW of strength (**A**) and spectral shape (α)~(e.g., α = -2/3)
 - Calculate simulated DS
 - On average, simulated DS increases as A increases
- Find value of A₉₅ such that 95% of the time the simulated DS exceeds the observed DS: This is the 95% confidence limit.

Parkes Pulsar Timing Array 2

- Monitoring 20 millisecond pulsars since 2005
 - Many pulsars extended using archival data
- Multi-frequency observation to mitigate interstellar propagation (Keith et al. 2013)

Parkes Pulsar Timing Array

- Monitoring 20 millisecond pulsars since 2005
 - Many pulsars extended using archival data
- Multi-frequency observation to mitigate interstellar propagation (Keith et al. 2013)

Power spectra of *best* PPTA Pulsars

These pulsars dominate the limit.

Only PSR J1713+0747 has additional modelled red noise

The Combined PPTA Limit

With 95% confidence (α =-2/3) A₉₅ < (2.4 \pm 0.1)x10⁻¹⁵

Limits for other types of GWB ($\alpha = -1$; $A_{95} < 10^{-15}$) ($\alpha = -7/6$; $A_{95} < 0.7 \times 10^{-15}$)

PPTA Limit on Background

The GWB in the Millennium Paradigm (Ravi et al. 2012 ApJ)

- Use Millennium dark matter simulations to trace large scale structure and evolution
- Use Semi-analytic model (Guo et al. 2011) for galaxy+SMBH formation and evolution.
- Produce self-consistent model for GW signal:
 - Matches evolution/growth of structure in universe
 - Quasar luminosities function, star formation rate
- Add in GWs
 - Coalescence by merger alone
 - Circular orbits
- Produces modestly non-Gaussian background

Springel et al. (2006)

SMBHs are bigger than previously thought

 $M_{BH} (M_{\odot})$

- New black hole mass function
 - Revised measurements of black hole-bulge mass relationship (McConnell & Ma 2012)
 - Average black hole mass increases by factor of 1.8
 - Can change masses of SMBH without affecting selfconsistency of models

Comparing models to the PPTA Limit

- McWilliams et al. (2012)
 - Assumes all growth (both in galaxies and black holes) is merger-driven at z < 1
 - Rule out model with ~ 90% confidence
- Sesana (2013)
 - Survey plausible range for GWB strength
 - Based on all observational uncertainties
 - Exclude~ 45% of parameter space
- Investigating the millennium paradigm
 - Non-Gaussian limit A < 2.7x10⁻¹⁵
 - Use millennium dark matter simulations + accompanying semi-analytic models
 - This paradigm set to match all electromagnetic observation (star formation rate, quasar luminosity function)

Ways to modify the SMBH background

- Environment
 - Plays a role in solving "final parsec" problem,
 - Q: Does it influence signal at 10 nHz?
 - A: Maybe. If centres of galaxies are full of stars, can attenuate signal
- Eccentricity
 - Eccentric binaries circularise by the time they reach PTA band, unless environment takes hold
- Mass and merger rate.
 - SMBH masses getting larger (largest SMBH grown through mergers)

24 | Astrophysical applications of pulsar timing arrays | Ryan Shannon

Searching for continuous-wave sources

- If there is a binary system that is sufficiently massive and sufficiently close its signal may be detected: continuous wave
- Example: Realisation of GWB from Ravi et al. (2012):
 - 1-2 of 100 realizations of the GWB has a strong nearby single source

Limits on continuous gravitational waves

- Arzoumanian et al, submitted. (Study led by Justin Ellis, UWM).
- Search NANOGrav 5-year datasets using Bayesian and frequentist methodolgy

Improving Sensitivity: short-term

- International Pulsar Timing Array
- Improved instrumentation
 - Wide (radiofrequency) bandwidth receiving systems
 - Increases sensitivity, observing throughput, better correction for refractive interstellar medium
- Additional telescope time
 - Increase sensitivity
 - Better understand systematics / improve calibration of the signal
- Observe more pulsars
 - Large-area sky surveys for new pulsars
- Optimise scheduling

Effelsberg ultra broad-band feed

Improving Sensitivity: longer-term

- New Facilities on the horizon:
- MeerKAT Array (South Africa)
 - 100-metre class interferometer
- Qitai Radio Telecope (XInjiang, China)
 - 100-metre class single dish
- Five-hundred metre Aperture Spherical Telescope (FAST, Guizhou, China),
 - 300-metre class single dish
- Square Kilometre Array:
 - 10x FAST
- •
- Need to account for astrophysical noise when developing hardware / scheduling observations on new telescopes

Summary

- Our understanding of astrophysical noise is improving and guiding PTA observations
- Limits on GWB are being used to constrain the massive black hole population. We can now test models of galaxy evolution.
- IPTA dataset should immediately improve limit
- New facilities / longer datasets /more pulsars will enable us to detect GWs with pulsars.
- Thank you
